1 Do-calculus for cyclic graphs

For completeness, we here repeat the rules of *do*-calculus for cyclic graphs, in the notation of the generalized ID algorithm of [2], which generalizes [5]. We are given a causal graph G . To each node X_i which is intervened upon, we add an ‘intervention node’ I_{X_i} , with a directed edge from I_{X_i} to X_i that we clamp to the value x_i . The corresponding graph is called \hat{G}^+ . $\hat{G}_{do(\mathbf{W})}$ is now obtained by removing from \hat{G}^+ all incoming edges to variables that are part of \mathbf{W} , except those from the corresponding intervention nodes $I_{\mathbf{W}}$. We use shorthand

$$\mathbf{Y} \overset{\sigma}{\perp\!\!\!\perp}_G \mathbf{X} \mid \mathbf{Z}, do(\mathbf{W})$$

to indicate that \mathbf{Y} and \mathbf{X} are σ -separated by \mathbf{Z} in the graph $\hat{G}_{do(\mathbf{W})}$. σ -separation is a generalization of standard d-separation (see [2] for details).

Do-calculus now consists of the following three inference rules that can be used to map interventional and observational distributions.

1. Insertion/deletion of observation:

$$P(\mathbf{Y} \mid \mathbf{X}, \mathbf{Z}, do(\mathbf{W})) = P(\mathbf{Y} \mid \mathbf{Z}, do(\mathbf{W})) \text{ if } \mathbf{Y} \overset{\sigma}{\perp\!\!\!\perp}_G \mathbf{X} \mid \mathbf{Z}, do(\mathbf{W}).$$

2. Action/observation exchange:

$$P(\mathbf{Y} \mid do(\mathbf{X}), \mathbf{Z}, do(\mathbf{W})) = P(\mathbf{Y} \mid \mathbf{X}, \mathbf{Z}, do(\mathbf{W})) \text{ if } \mathbf{Y} \overset{\sigma}{\perp\!\!\!\perp}_G I_{\mathbf{X}} \mid \mathbf{X}, \mathbf{Z}, do(\mathbf{W}).$$

3. Insertion/deletion of actions:

$$P(\mathbf{Y} \mid do(\mathbf{X}), \mathbf{Z}, do(\mathbf{W})) = P(\mathbf{Y} \mid \mathbf{Z}, do(\mathbf{W})) \text{ if } \mathbf{Y} \overset{\sigma}{\perp\!\!\!\perp}_G I_{\mathbf{X}} \mid \mathbf{Z}, do(\mathbf{W}).$$

Through consecutive application of these rules, we can try to turn any interventional probability of interest into an observational probability.

2 Shapley values for linear models

We will make use of the *do*-calculus rules above to derive the causal Shapley values for the four different models in Figure 1 in the main text. To this end, we consider the three models in Figure 1 that predict $f(x_1, x_2) = \beta_1 x_1 + \beta_2 x_2$ for general values of β_1 and β_2 . All three models have the same observational probability distribution, with $\mathbb{E}[X_i] = \bar{x}_i$ and $\mathbb{E}[X_{3-i}] = \alpha_i x_i$, for $i = 1, 2$, yet different

Figure 1: Three causal models with the same observational distribution over features, yet a different causal structure. To connect to the models in the main text, we set $\beta_1 = 0$ and $\beta_2 = \beta$, except that for the ‘fork’ we set $\beta_2 = 0$, $\beta_1 = \beta$, and then swap the indices.

causal structures. We will arrive at the main text’s results for the ‘chain’, ‘confounder’, and ‘cycle’ by setting $\beta_1 = 0$, whereas for the ‘fork’ we set $\beta_2 = 0$ and swap the two indices. We then further need to take $\bar{x}_1 = \bar{x}_2 = 0$, and $\alpha = \alpha_2$.

Following the definitions in the main text, the contribution of feature i given permutation π is the difference in value function before and after setting the feature to its value:

$$\phi_i(\pi) = v(\{j : j \leq_\pi i\}) - v(\{j : j <_\pi i\}), \quad (1)$$

with value function

$$v(S) = \mathbb{E}[f(\mathbf{X}) | do(\mathbf{X}_S = \mathbf{x}_S)] = \int d\mathbf{X}_{\bar{S}} P(\mathbf{X}_{\bar{S}} | \hat{\mathbf{x}}_S) f(\mathbf{X}_{\bar{S}}, \mathbf{x}_S), \quad (2)$$

where we use shorthand $\hat{\mathbf{x}}$ for $do(\mathbf{X} = \mathbf{x})$. Combining these two definitions and substituting $f(\mathbf{x}) = \sum_i \beta_i x_i$, we obtain

$$\phi_i(\pi) = \beta_i (x_i - \mathbb{E}[X_i | \hat{\mathbf{x}}_{j:j <_\pi i}]) + \sum_{k >_\pi i} \beta_k (\mathbb{E}[X_k | \hat{\mathbf{x}}_{j:j \leq_\pi i}] - \mathbb{E}[X_k | \hat{\mathbf{x}}_{j:j <_\pi i}]).$$

The first term corresponds to the direct effect, the second one to the indirect effect. Symmetric causal Shapley values will follow by averaging these contributions for the two possible permutations $\pi = (1, 2)$ and $\pi = (2, 1)$. Conditional Shapley values result when replacing conditioning by intervention with conventional conditioning by observation, marginal Shapley values by not conditioning at all.

To start with the latter, we immediately see that for *marginal Shapley values* the indirect effect vanishes and the direct effect simplifies to

$$\phi_i = \phi_i(\pi) = \beta_i (x_i - \mathbb{E}[X_i]) = \beta_i (x_i - \bar{x}_i),$$

as also derived in [1].

For symmetric conditional Shapley values, we do get different contributions for the two different permutations, but by definition still the same for the three different models:

$$\begin{aligned} \phi_1(1, 2) &= \beta_1 (x_1 - \mathbb{E}[X_1]) + \beta_2 (\mathbb{E}[X_2 | x_1] - \mathbb{E}[X_2]) = \beta_1 (x_1 - \bar{x}_1) + \beta_2 \alpha_1 (x_1 - \bar{x}_1) \\ \phi_2(1, 2) &= \beta_2 (x_2 - \mathbb{E}[X_2 | x_1]) = \beta_2 (x_2 - \bar{x}_2) - \beta_2 \alpha_1 (x_1 - \bar{x}_1). \end{aligned} \quad (3)$$

Here the first term in the contribution for the first feature corresponds to the direct effect and the second term to the indirect effect. The contribution for the second feature only consists of a direct effect. The contributions for the other permutation follow by swapping the indices and the final Shapley values by averaging to arrive at the *symmetric conditional Shapley values*

$$\begin{aligned} \phi_1 &= \beta_1 (x_1 - \bar{x}_1) - \frac{1}{2} \beta_1 \alpha_2 (x_2 - \bar{x}_2) + \frac{1}{2} \beta_2 \alpha_1 (x_1 - \bar{x}_1) \\ \phi_2 &= \beta_2 (x_2 - \bar{x}_2) - \frac{1}{2} \beta_2 \alpha_1 (x_1 - \bar{x}_1) + \frac{1}{2} \beta_1 \alpha_2 (x_2 - \bar{x}_2), \end{aligned} \quad (4)$$

where now the first two terms constitute the direct effect and the third term the indirect effect.

expectation	chain	confounder	cycle
$\mathbb{E}[X_1 \hat{x}_2]$	$\mathbb{E}[X_1]$	$\mathbb{E}[X_1]$	$\mathbb{E}[X_1 x_2]$
$\mathbb{E}[X_2 \hat{x}_1]$	$\mathbb{E}[X_2 x_1]$	$\mathbb{E}[X_2]$	$\mathbb{E}[X_2 x_1]$

Table 1: Turning expectations under conditioning by intervention into expectations under conventional conditioning by observation for the three models in Figure 1.

44 The *asymmetric conditional Shapley values* consider both permutations for the confounder and the
 45 cycle, and hence are equivalent to the symmetric Shapley values for those models. Yet for the chain,
 46 they only consider the permutation $\pi(1, 2)$ and thus yield $\phi = \phi(1, 2)$ from (5).

47 To go from the symmetric conditional Shapley values to the causal symmetric Shapley values, we
 48 follow the same line of reasoning, but have to replace $\mathbb{E}[X_2|x_1]$ by $\mathbb{E}[X_2|\hat{x}_1]$ and $\mathbb{E}[X_1|x_2]$ by $\mathbb{E}[X_1|\hat{x}_2]$.
 49 Table 1 tells whether the expectations under conditioning by intervention reduce to expectations
 50 under conditioning by observation (because of the second rule of *do*-calculus above) or to marginal
 51 expectations (because of the third rule). For the chain we have

$$P(X_2|\hat{x}_1) = P(X_2|x_1) \text{ since } X_2 \stackrel{\sigma}{\perp\!\!\!\perp}_G I_{X_1} | X_1 \text{ (rule 2), yet } P(X_1|\hat{x}_2) = P(X_1) \text{ since } X_1 \stackrel{\sigma}{\perp\!\!\!\perp}_G I_{X_2} \text{ (rule 3),}$$

52 for the confounder

$$P(X_2|\hat{x}_1) = P(X_2) \text{ since } X_2 \stackrel{\sigma}{\perp\!\!\!\perp}_G I_{X_1} \text{ and } P(X_1|\hat{x}_2) = P(X_1) \text{ since } X_1 \stackrel{\sigma}{\perp\!\!\!\perp}_G I_{X_2} \text{ (rule 3),}$$

53 and for the cycle

$$P(X_2|\hat{x}_1) = P(X_2|x_1) \text{ since } X_2 \stackrel{\sigma}{\perp\!\!\!\perp}_G I_{X_1} | X_1 \text{ and } P(X_1|\hat{x}_2) = P(X_1|x_2) \text{ since } X_1 \stackrel{\sigma}{\perp\!\!\!\perp}_G I_{X_2} | X_2 \text{ (rule 2).}$$

54 Consequently, for the confounder the *symmetric* and *asymmetric causal Shapley values* coincide with
 55 the marginal Shapley values (consistent with [4]) and for the cycle with the symmetric conditional
 56 Shapley values from (4). For the chain, the causal symmetric Shapley values become

$$\begin{aligned} \phi_1(1, 2) &= \beta_1(x_1 - \bar{x}_1) + \frac{1}{2}\beta_2\alpha_1(x_1 - \bar{x}_1) \\ \phi_2(1, 2) &= \beta_2(x_2 - \bar{x}_2) - \frac{1}{2}\beta_2\alpha_1(x_1 - \bar{x}_1), \end{aligned} \tag{5}$$

57 where the asymmetric causal Shapley values coincides with the asymmetric conditional Shapley
 58 values from (5).

59 Collecting all results and setting $\bar{x}_1 = \bar{x}_2 = \beta_1 = 0, \beta_2 = \beta$, and $\alpha_1 = \alpha$ (after swapping the indices for
 60 the ‘fork’), we arrive at the Shapley values reported in Figure 1 in the main text. Note that for most
 61 Shapley values, the indirect effect for the second feature vanishes because we chose to set $\beta_1 = 0$.
 62 The exceptions, apart from the marginal Shapley values, are the causal Shapley values for the chain
 63 and the confounder, as well as the asymmetric conditional Shapley values for the chain: these show
 64 no indirect effect for the second feature even for nonzero β_1 .

65 3 Proofs and corollaries on causal chain graphs

66 In this section we expand on the proof of Theorem 1 in the main text and add some corollaries to link
 67 back to other approaches for computing Shapley values.

68 The probability distribution for a causal chain graph boils down to a directed acyclic graph of chain
 69 components:

$$P(\mathbf{X}) = \prod_{\tau \in \mathcal{T}} P(\mathbf{X}_\tau | \mathbf{X}_{pa(\tau)}). \tag{6}$$

70 For each (fully connected) chain component, we further need to specify whether (surplus) depen-
 71 dencies within the component are due to confounding or due to mutual interactions. Given this
 72 information, we can turn any causal query into an observational distribution with the following
 73 interventional formula.

74 **Theorem 1.** *For causal chain graphs, we have the interventional formula*

$$P(\mathbf{X}_S | do(\mathbf{X}_S = \mathbf{x}_S)) = \prod_{\tau \in \mathcal{T}_{\text{confounding}}} P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}) \times \prod_{\tau \in \overline{\mathcal{T}_{\text{confounding}}}} P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}, \mathbf{x}_{\tau \cap S}). \quad (7)$$

75 *Proof.* Plugging in (6) and using shorthand $\hat{\mathbf{x}} = do(\mathbf{X} = \mathbf{x})$, we obtain

$$P(\mathbf{X}_S | \hat{\mathbf{x}}_S) = P(\mathbf{X} | \hat{\mathbf{x}}_S) = \prod_{\tau \in \mathcal{T}} P(\mathbf{X}_\tau | \mathbf{X}_{\tau' <_G \tau}, \hat{\mathbf{x}}_S) \stackrel{(1)}{=} \prod_{\tau \in \mathcal{T}} P(\mathbf{X}_\tau | \mathbf{X}_{pa(\tau)}, \hat{\mathbf{x}}_S) = \prod_{\tau \in \mathcal{T}} P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_S),$$

76 where in the second step we made use of *do*-calculus rule (1): the conditional independencies in the
77 causal chain graph G are preserved when we intervene on some of the variables. Now rule (3) tells us
78 that we can ignore any interventions from nodes in components further down the causal chain graph
79 as well as those from higher up that are shielded by the direct parents:

$$P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_S) \stackrel{(3)}{=} P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{\tau \cap S}).$$

80 Rule (2) then states that conditioning by intervention upon variables higher up in the causal chain
81 graph is equivalent to conditioning by observation:

$$P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{\tau \cap S}) \stackrel{(2)}{=} P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{\tau \cap S}).$$

82 For a chain component with dependencies induced by a common confounder, rule (3) applies once
83 more and makes that we can ignore the interventions:

$$P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{\tau \cap S}) = P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}).$$

84 For a chain component with dependencies induced by mutual interactions, rule (2) again applies and
85 allows us to replace conditioning by intervention with conditioning by observation:

$$P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}, \hat{\mathbf{x}}_{\tau \cap S}) = P(\mathbf{X}_{\tau \cap S} | \mathbf{X}_{pa(\tau) \cap S}, \mathbf{x}_{pa(\tau) \cap S}, \mathbf{x}_{\tau \cap S}).$$

86 □

87 Algorithm 1 provides pseudocode on how to estimate the value function $v(S)$ by drawing samples
88 from the interventional probability (7). It assumes that a user has specified a partial causal ordering
89 of the features, which is translated to a chain graph with components \mathcal{T} , and for each (non-singleton)
90 component τ whether or not surplus dependencies are the result of confounding. Other prerequisites
91 include access to the model $f()$, the feature vector \mathbf{x} , (a procedure to sample from) the observational
92 probability distribution $P(\mathbf{X})$, and the number of samples N_{samples} .

93 Theorem 1 connects to observations made and algorithms proposed in recent papers.

94 **Corollary 1.** *With all features combined in a single component and all dependencies induced by*
95 *confounding, as in [4], causal Shapley values are equivalent to marginal Shapley values.*

96 *Proof.* With just a single confounded component τ , $pa(\tau) = \emptyset$ and (7) reduces to $P(\mathbf{X}_S)$. □

97 **Corollary 2.** *With all features combined in a single component and all dependencies induced by*
98 *mutual interactions, causal Shapley values are equivalent to conditional Shapley values as proposed*
99 *in [1].*

100 *Proof.* With just a single non-confounded component τ , $pa(\tau) = \emptyset$ and (7) reduces to $P(\mathbf{X}_S | \mathbf{x}_S)$. □

101 **Corollary 3.** *When we only take into account permutations that match the causal ordering and*
102 *assume that all dependencies within chain components are induced by mutual interactions, the*
103 *resulting asymmetric causal Shapley values are equivalent to the asymmetric conditional Shapley*
104 *values as defined in [3].*

Algorithm 1 Compute the value function $v(S)$ under conditioning by intervention.

12:  end for
13:   $v \leftarrow \frac{1}{N_{\text{samples}}} \sum_{k=1}^{N_{\text{samples}}} f(\mathbf{x}_S, \tilde{\mathbf{x}}_{\bar{S}}^{(k)})$ 
14:  return  $v$ 
15: end function

```

105 *Proof.* Following [3], asymmetric Shapley values only include those permutations π for which $i <_{\pi} j$
 106 for all known ancestors i of descendants j in the causal graph. For those permutations, we are
 107 guaranteed to have $\tau <_G \tau'$ for all $\tau, \tau' \in \mathcal{T}$ such that $\tau \cap S \neq \emptyset, \tau' \cap \bar{S} \neq \emptyset$. That is, the chain
 108 components that contain features from S are never later in the causal ordering of the chain graph G
 109 than those that contain features from \bar{S} . We then have

$$P(\mathbf{X}_{\bar{S}} | \mathbf{x}_S) = \prod_{\tau \in \mathcal{T}} P(\mathbf{X}_{\tau \cap \bar{S}} | \mathbf{X}_{pa(\tau) \cap \bar{S}}, \mathbf{x}_S) = \prod_{\tau \in \mathcal{T}} P(\mathbf{X}_{\tau \cap \bar{S}} | \mathbf{X}_{pa(\tau) \cap \bar{S}}, \mathbf{x}_{pa(\tau) \cap S}, \mathbf{x}_{\tau \cap S}) = P(\mathbf{X}_{\bar{S}} | \hat{\mathbf{x}}_S),$$

110 where in the last step we used interventional formula (7) in combination with the fact that $\mathcal{T}_{\text{confounding}} =$
 111 \emptyset . □

112 4 Additional illustrations on the bike rental data

113 Figure 2 shows sina plots for asymmetric conditional Shapley values (left) and marginal Shapley
 114 values (right), to be compared with the sina plots for symmetric causal Shapley values in Figure 3
 115 of the main text. In this case, the sina plots for asymmetric causal Shapley values are virtually
 116 indistinguishable from those for the asymmetric conditional Shapley values.

117 It can be seen that the marginal Shapley values strongly focus on temperature, largely ignoring the
 118 seasonal variables. The asymmetric Shapley values do the opposite: they focus on the seasonal
 119 variables, in particular *cosyear* and put much less emphasis on the temperature variables.

120 5 Comparing symmetric and asymmetric Shapley values on the XOR 121 problem

122 We consider the standard XOR problem with binary features X_1 and X_2 and binary output Y :

X_1	X_2	Y
0	0	0
0	1	1
1	0	1
1	1	0

123
 124 We generate a dataset of n samples by drawing features and corresponding outputs with probabilities
 125 $p_{ij} = P(X_1 = i, X_2 = j)$. We will choose $p_{00} = p_{11} = \frac{1}{4}(1 + \epsilon)$ and $p_{01} = p_{10} = \frac{1}{4}(1 - \epsilon)$. With
 126 $\epsilon > 0$, the probability of the two features having the same values is larger than the probability of them
 127 having different values. \hat{p}_{ij} is the same probability estimated from the data, e.g., by computing the

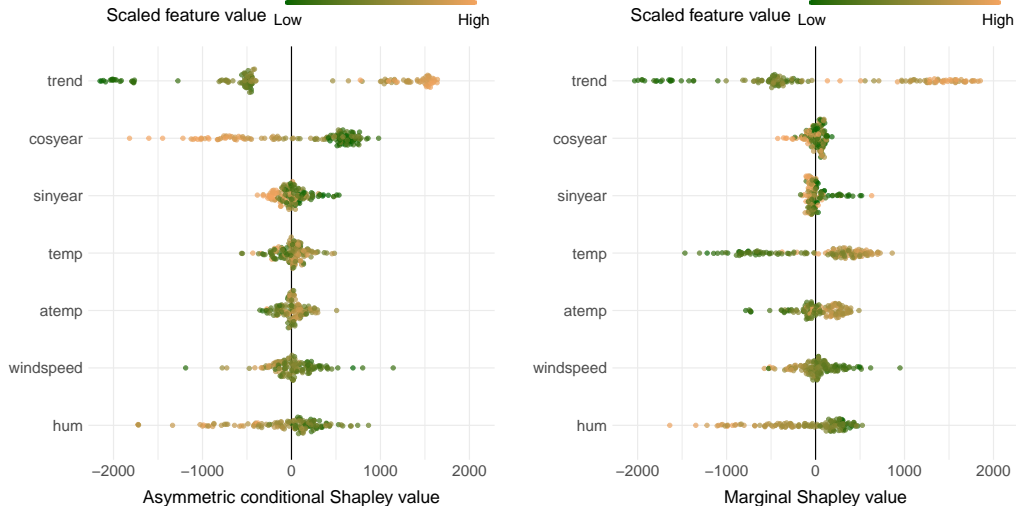

Figure 2: Sina plots of asymmetric (conditional) Shapley values (left) and marginal Shapley values (right). See Figure 3 in the main text for further details.

128 frequencies of the four input combinations. We train a neural network on the generated data, which
 129 yields a function $\hat{f}(X_1, X_2)$ hopefully closely approximating the correct XOR function.

130 We will now compute the various Shapley values for the data point $(X_1, X_2) = (0, 0)$. The value
 131 functions with all features either ‘out-of-coalition’ or ‘in-coalition’ are the same for all Shapley
 132 values:

$$\begin{aligned} v(\{\}) &= \mathbb{E}[f(\mathbf{X})] = \sum_{i,j} \hat{p}_{ij} \hat{f}(i, j) \approx \frac{1}{2}(1 - \epsilon) \\ v(\{1, 2\}) &= \hat{f}(0, 0) \approx 0, \end{aligned}$$

133 where we use the convention that the Shapley values computed from the fitted probabilities and
 134 learned neural network appear before the \approx -sign, and those that we obtain when the fitted probabilities
 135 equal the probabilities used to generate the data and when the learned neural network equals the XOR
 136 function after the \approx -sign.

137 The value functions for the case that one input is ‘in-coalition’ and the other ‘out-of-coalition’ does
 138 depend on the type of Shapley value under consideration. For the marginal Shapley values we get

$$\begin{aligned} v(\{1\}) &= \mathbb{E}[f(0, X_2)] = \sum_j \left(\sum_i \hat{p}_{ij} \right) \hat{f}(0, j) \approx \frac{1}{2} \\ v(\{2\}) &= \mathbb{E}[f(X_1, 0)] = \sum_i \left(\sum_j \hat{p}_{ij} \right) \hat{f}(i, 0) \approx \frac{1}{2}, \end{aligned} \quad (8)$$

139 yet for the conditional Shapley values

$$\begin{aligned} v(\{1\}) &= \mathbb{E}[f(0, X_2) | X_1 = 0] = \sum_j \frac{\hat{p}_{0j}}{\sum_i \hat{p}_{ij}} \hat{f}(0, j) \approx \frac{1}{2}(1 - \epsilon) \\ v(\{2\}) &= \mathbb{E}[f(X_1, 0) | X_2 = 0] = \sum_i \frac{\hat{p}_{i0}}{\sum_j \hat{p}_{ij}} \hat{f}(i, 0) \approx \frac{1}{2}(1 - \epsilon). \end{aligned} \quad (9)$$

140 The value functions for the causal Shapley values depend on the presumed causal model that generates
 141 the dependencies. In case the dependencies are assumed to be the result of confounding, we get the
 142 value functions in (8) as for the marginal Shapley values and when the dependencies are assumed to
 143 be the result of mutual interaction the value functions in (9) as for the conditional Shapley values.

144 The more interesting case is when we assume a causal chain, e.g., $X_1 \rightarrow X_2$:

$$\begin{aligned} v(\{1\}) &= \mathbb{E}[f(0, X_2)|do(X_1 = 0)] = \mathbb{E}[f(0, X_2)|X_1 = 0] = \sum_j \frac{\hat{p}_{0j}}{\sum_i \hat{p}_{ij}} \hat{f}(0, j) \approx \frac{1}{2}(1 - \epsilon) \\ v(\{2\}) &= \mathbb{E}[f(X_1, 0)|do(X_2 = 0)] = \mathbb{E}[f(X_1, 0)] = \sum_i \left(\sum_j \hat{p}_{ij} \right) \hat{f}(i, 0) \approx \frac{1}{2}, \end{aligned} \quad (10)$$

145 and the same with indices 1 and 2 interchanged for the causal chain $X_2 \rightarrow X_1$.

146 Given these value functions, we can now compute the various Shapley values. For marginal and
147 symmetric Shapley values we have

$$\begin{aligned} \phi_1 &= \frac{1}{2}[v(\{1\}) - v(\{\})] + \frac{1}{2}[v(\{1, 2\}) - v(\{2\})] \\ \phi_2 &= \frac{1}{2}[v(\{2\}) - v(\{\})] + \frac{1}{2}[v(\{1, 2\}) - v(\{1\})], \end{aligned}$$

148 whereas for asymmetric Shapley values, assuming the causal chain $X_1 \rightarrow X_2$,

$$\begin{aligned} \phi_1 &= v(\{1\}) - v(\{\}) \\ \phi_2 &= v(\{1, 2\}) - v(\{1\}), \end{aligned}$$

149 and the same with indices 1 and 2 interchanged for the causal chain $X_2 \rightarrow X_1$.

150 With the expressions above, we can compute the various Shapley values based on a learned neural
151 network and the actual frequencies of the generated feature combinations and compare those with the
152 theoretical values obtained when the estimated frequencies equal the probabilities used to generate the
153 data and the neural network indeed managed to learn the XOR function. For the latter we distinguish
154 the following cases.

155 **identical:** $\phi_1 = \phi_2 \approx \frac{1}{4}\epsilon - \frac{1}{4}$. This applies to marginal, symmetric conditional, symmetric causal
156 assuming confounding, symmetric causal assuming mutual interaction.

157 **symmetric causal:** $\phi_1 \approx -\frac{1}{4}$ and $\phi_2 \approx \frac{1}{2}\epsilon - \frac{1}{4}$ assuming the causal chain $X_1 \rightarrow X_2$ and vice versa for
158 $X_1 \rightarrow X_2$.

159 **asymmetric:** $\phi_1 \approx 0$ and $\phi_2 \approx \frac{1}{2}\epsilon - \frac{1}{2}$ assuming the causal chain $X_1 \rightarrow X_2$ and vice versa for
160 $X_1 \rightarrow X_2$. These apply both to asymmetric conditional and asymmetric causal.

161 In this example, symmetric causal Shapley values are clearly to be preferred over asymmetric causal
162 Shapley values. Inserting a causal link with zero strength ($\epsilon = 0$), asymmetric Shapley values jump
163 from the symmetric $\phi_1 = \phi_2 \approx -\frac{1}{4}$ to the completely asymmetric $\phi_1 \approx 0$ and $\phi_2 \approx -\frac{1}{2}$, assigning
164 all credit to the second variable, even though the first feature in reality does not affect the second
165 feature at all. Symmetric Shapley values, on the other hand, are insensitive to the insertion of a causal
166 link with zero strength: in the limit $\epsilon \rightarrow 0$ symmetric causal Shapley values correctly converge to
167 marginal Shapley values.
